## Lecture #7 – High-Dimensional Regression I

**QR** Decomposition

Singular Value Decomposition

Ridge Regression

## **QR** Decomposition

#### Result

Any  $n \times k$  matrix A with full column rank can be decomposed as A = QR, where R is an  $k \times k$  upper triangular matrix and Q is an  $n \times k$  matrix with orthonormal columns.

#### Notes

- ► Columns of A are *orthogonalized* in Q via Gram-Schmidt.
- ▶ Since Q has orthogonal columns,  $Q'Q = I_k$ .
- ▶ It is *not* in general true that QQ' = I.
- ▶ If A is square, then  $Q^{-1} = Q'$ .

## Different Conventions for the QR Decomposition

#### Thin aka Economical QR

Q is an  $n \times k$  with orthonormal columns (qr\_econ in Armadillo).

#### Thick QR

Q is an  $n \times n$  orthogonal matrix.

### Relationship between Thick and Thin

Let A = QR be the "thick" QR and  $A = Q_1R_1$  be the "thin" QR:

$$A = QR = Q \begin{bmatrix} R_1 \\ 0 \end{bmatrix} = \begin{bmatrix} Q_1 & Q_2 \end{bmatrix} \begin{bmatrix} R_1 \\ 0 \end{bmatrix} = Q_1R_1$$

My preferred convention is the thin QR...

## Least Squares via QR Decomposition

Let 
$$X = QR$$

$$\widehat{\beta} = (X'X)^{-1}X'y = [(QR)'(QR)]^{-1}(QR)'y$$

$$= [R'Q'QR]^{-1}R'Q'y = (R'R)^{-1}R'Qy$$

$$= R^{-1}(R')^{-1}R'Q'y = R^{-1}Q'y$$

In other words,  $\widehat{\beta}$  solves  $R\beta = Q'y$ .

#### Why Bother?

Much easier and faster to solve  $R\beta = Q'y$  than the normal equations  $(X'X)\beta = X'y$  since R is upper triangular.

### Back-Substitution to Solve $R\beta = Q'y$

The product Q'y is a vector, call it v, so the system is simply

$$\begin{bmatrix} r_{11} & r_{12} & r_{13} & \cdots & r_{1,n-1} & r_{1k} \\ 0 & r_{22} & r_{23} & \cdots & r_{2,n-1} & r_{2k} \\ 0 & 0 & r_{33} & \cdots & r_{3,n-1} & r_{3k} \\ \vdots & \vdots & \ddots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & 0 & r_{k-1,k-1} & r_{k-1,k} \\ 0 & 0 & \cdots & 0 & 0 & r_k \end{bmatrix} \begin{bmatrix} \beta_1 \\ \beta_2 \\ \beta_3 \\ \vdots \\ \beta_{k-1} \\ \beta_k \end{bmatrix} = \begin{bmatrix} v_1 \\ v_2 \\ v_3 \\ \vdots \\ v_{k-1} \\ v_k \end{bmatrix}$$

 $\beta_k = v_k/r_k \Rightarrow$  substitute this into  $\beta_{k-1}r_{k-1,k-1} + \beta_k r_{k-1,k} = v_{k-1}$  to solve for  $\beta_{k-1}$ , and so on.

# Calculating the Least Squares Variance Matrix $\sigma^2(X'X)^{-1}$

- ► Since X = QR,  $(X'X)^{-1} = R^{-1}(R^{-1})'$
- ► Easy to invert *R*: just apply repeated back-substitution:
  - ▶ Let  $A = R^{-1}$  and  $\mathbf{a}_i$  be the *j*th column of A.
  - ▶ Let  $\mathbf{e}_j$  be the *j*th standard basis vector.
  - Inverting R is equivalent to solving  $R\mathbf{a}_1 = \mathbf{e}_1$ , followed by  $R\mathbf{a}_2 = \mathbf{e}_2, \ldots, R\mathbf{a}_k = \mathbf{e}_k$ .
- ▶ If you enclose a matrix in trimatu() or trimatl(), and request the inverse ⇒ Armadillo will carry out backward or forward substitution, respectively.

## QR Decomposition for Orthogonal Projections

Let X have full column rank and define  $P_X = X(X'X)^{-1}X'$ 

$$P_X = QR(R'R)^{-1}R'Q' = QRR^{-1}(R')^{-1}R'Q' = QQ'$$

It is *not* in general true that QQ'=I even though Q'Q=I since Q need not be square in the economical QR decomposition.

# The Singular Value Decomposition (SVD)

Any  $m \times n$  matrix A of arbitrary rank r can be written

$$A = UDV' = (orthogonal)(diagonal)(orthogonal)$$

- $V = m \times m$  orthog. matrix whose cols contain e-vectors of AA'
- $V = n \times n$  orthog. matrix whose cols contain e-vectors of A'A
- ▶  $D = m \times n$  matrix whose first r main diagonal elements are the *singular values*  $d_1, \ldots, d_r$ . All other elements are zero.
- ▶ The singular values  $d_1, ..., d_r$  are the square roots of the non-zero eigenvalues of A'A and AA'.
- $\blacktriangleright$  (E-values of A'A and AA' could be zero but not negative)

# SVD for Symmetric Matrices

If A is **symmetric** then  $A = Q\Lambda Q'$  where  $\Lambda$  is a diagonal matrix containing the e-values of A and Q is an orthonormal matrix whose columns are the corresponding e-vectors. Accordingly:

$$AA' = (Q \wedge Q')(Q \wedge Q')' = Q \wedge Q'Q \wedge Q' = Q \wedge^2 Q'$$

and similarly

$$A'A = (Q \wedge Q')'(Q \wedge Q') = Q \wedge Q'Q \wedge Q' = Q \wedge^2 Q'$$

using the fact that Q is orthogonal and  $\Lambda$  diagonal. Thus, when A is symmetric the SVD reduces to U=V=Q and  $D=\sqrt{\Lambda^2}$  so that *negative* eigenvalues become *positive* singular values.

### The Economical SVD

- ▶ Number of singular values is  $r = Rank(A) \le max\{m, n\}$
- ▶ Some cols of *U* or *V* multiplied by zeros in *D*
- Economical SVD: only keep columns in U and V that are multiplied by non-zeros in D (Armadillo: svd\_econ)
- ▶ Summation form:  $A = \sum_{i=1}^r d_i \mathbf{u}_i \mathbf{v}_i'$  where  $d_1 \leq d_2 \leq \cdots \leq d_r$
- ► Matrix form: A = U D V' $(n \times p) = (n \times r)(r \times r)(r \times p)$

In the economical SVD, U and V may no longer be square, so they are not orthogonal matrices but their *columns* are still orthonormal.

## Ridge Regression – OLS with an $L_2$ Penalty

$$\widehat{\beta}_{\textit{Ridge}} = \operatorname*{arg\,min}_{\beta} \, (\mathbf{y} - X\beta)'(\mathbf{y} - X\beta) + \lambda \beta' \beta$$

- Add a penalty for large coefficients
- $lacktriangleright \lambda = ext{non-negative constant}$  we choose: strength of penalty
- $\triangleright$  X and **y** assumed to be de-meaned (don't penalize intercept)
- ▶ Unlike OLS, Ridge Regression is not scale invariant
  - ▶ In OLS if we replace  $\mathbf{x}_1$  with  $c\mathbf{x}_1$  then  $\beta_1$  becomes  $\beta_1/c$ .
  - ▶ The same is not true for ridge regression!
  - ► Typical to standardize *X* before carrying out ridge regression

## Alternative Formulation of Ridge Regression Problem

$$\widehat{eta}_{\mathit{Ridge}} = \operatorname*{arg\,min}_{eta} \ (\mathbf{y} - Xeta)'(\mathbf{y} - Xeta) \quad \text{subject to} \quad eta'eta \leq t$$

- ▶ Ridge Regression is like least squares "on a budget."
- ► Make one coefficient larger ⇒ must make another one smaller.
- ▶ One-to-one mapping from t to  $\lambda$  (data-dependent)

## Ridge as Bayesian Linear Regression

If we ignore the intercept, which is unpenalized), Ridge Regression gives the posterior mode from the Bayesian regression model:

$$y|X, \beta, \sigma^2 \sim N(X\beta, \sigma^2 I_n)$$
  
 $\beta \sim N(\mathbf{0}, \tau^2 I_p)$ 

where  $\sigma^2$  is assumed known and  $\lambda = \sigma^2/\tau^2$ . (In this example, the posterior is normal so the mode equals the mean)

## Explicit Solution to the Ridge Regression Problem

Objective Function:

$$Q(\beta) = (\mathbf{y} - X\beta)'(\mathbf{y} - X\beta) + \lambda\beta'\beta$$

$$= \mathbf{y}'\mathbf{y} - \beta'X\mathbf{y} - \mathbf{y}'X\beta + \beta'X'X\beta + \lambda\beta'I_{p}\beta$$

$$= \mathbf{y}'\mathbf{y} - 2\mathbf{y}'X\beta + \beta'(X'X + \lambda I_{p})\beta$$

Recall the following facts about matrix differentiation

$$\partial (\mathbf{a}'\mathbf{x})/\partial \mathbf{x} = \mathbf{a}, \quad \partial (\mathbf{x}'A\mathbf{x})/\partial \mathbf{x} = (A+A')\mathbf{x}$$

Thus, since  $(X'X + \lambda I_p)$  is symmetric,

$$\frac{\partial}{\partial \beta} Q(\beta) = -2X' \mathbf{y} + 2(X'X + \lambda I_p)\beta$$

# Explicit Solution to the Ridge Regression Problem

Previous Slide:

$$\frac{\partial}{\partial \beta}Q(\beta) = -2X'\mathbf{y} + 2(X'X + \lambda I_p)\beta$$

First order condition:

$$X'\mathbf{y} = (X'X + \lambda I_p)\beta$$

Hence,

$$\widehat{eta}_{Ridge} = (X'X + \lambda I_p)^{-1}X'\mathbf{y}$$

But is  $(X'X + \lambda I_p)$  guaranteed to be invertible?

# Ridge Regresion via OLS with "Dummy Observations"

Ridge regression solution is identical to

$$\arg\min_{\boldsymbol{\beta}} \left(\widetilde{\mathbf{y}} - \widetilde{X}\boldsymbol{\beta}\right)' \left(\widetilde{\mathbf{y}} - \widetilde{X}\boldsymbol{\beta}\right)$$

where

$$\widetilde{\mathbf{y}} = \begin{bmatrix} \mathbf{y} \\ \mathbf{0}_p \end{bmatrix}, \qquad \widetilde{X} = \begin{bmatrix} X \\ \sqrt{\lambda} I_p \end{bmatrix}$$

since:

$$\left( \widetilde{\mathbf{y}} - \widetilde{X}\beta \right)' \left( \widetilde{\mathbf{y}} - \widetilde{X}\beta \right) = \left[ (\mathbf{y} - X\beta)' (-\sqrt{\lambda}\beta)' \right] \left[ \begin{array}{c} (\mathbf{y} - X\beta) \\ -\sqrt{\lambda}\beta \end{array} \right]$$

$$= (\mathbf{y} - X\beta)'(\mathbf{y} - X\beta) + \lambda\beta'\beta$$

## Ridge Regression Solution is Always Unique

Ridge solution is always unique, even if there are more regressors than observations! This follows from the preceding slide:

$$\begin{split} \widehat{\beta}_{\textit{Ridge}} &= \arg\min_{\beta} \left( \widetilde{\mathbf{y}} - \widetilde{X}\beta \right)' \left( \widetilde{\mathbf{y}} - \widetilde{X}\beta \right) \\ \widetilde{\mathbf{y}} &= \left[ \begin{array}{c} \mathbf{y} \\ \mathbf{0}_{p} \end{array} \right], \ \widetilde{X} = \left[ \begin{array}{c} X \\ \sqrt{\lambda}I_{p} \end{array} \right] \end{split}$$

Columns of  $\sqrt{\lambda}I_p$  are linearly independent, so columns of  $\widetilde{X}$  are also linearly independent, regardless of whether the same holds for the columns of X.

### Efficient Calculations for Ridge Regression

### **QR** Decomposition

Write Ridge as OLS with "dummy observations" with  $\widetilde{X} = QR$  so

$$\widehat{\beta}_{\mathit{Ridge}} = (\widetilde{X}'\widetilde{X})^{-1}\widetilde{X}'\widetilde{\mathbf{y}} = R^{-1}Q'\widetilde{\mathbf{y}}$$

which we can obtain by back-solving the system  $R\widehat{eta}_{Ridge} = Q'\,\widetilde{\mathbf{y}}.$ 

### Singular Value Decomposition

If  $p \gg n$ , it's much faster to use the SVD rather than the QR decomposition because the rank of X will be n. For implementation details, see Murphy (2012; Section 7.5.2).

## Comparing Ridge and OLS

#### Assumption

Centered data matrix  $X \atop (n \times p)$  with rank p so OLS estimator is unique.

#### **Economical SVD**

- $igwedge X = igcup_{(n \times p)} D V' \text{ with } U'U = V'V = I_p, \ D \text{ diagonal}$
- ► Hence:  $X'X = (UDV')'(UDV') = VDU'UDV' = VD^2V'$
- ▶ Since V is square it is an orthogonal matrix:  $VV' = I_p$

## Comparing Ridge and OLS – The "Hat Matrix"

Using X = UDV' and the fact that V is orthogonal,

$$H(\lambda) = X (X'X + \lambda I_p)^{-1} X' = UDV' (VD^2V + \lambda VV')^{-1} VDU'$$

$$= UDV' (VD^2V' + \lambda VV')^{-1} VDU'$$

$$= UDV' [V(D^2 + \lambda I_p)V']^{-1} VDU'$$

$$= UDV' (V')^{-1} (D^2 + \lambda I_p)^{-1} (V)^{-1} VDU'$$

$$= UDV'V (D^2 + \lambda I_p)^{-1} V'VDU'$$

$$= UD (D^2 + \lambda I_p)^{-1} DU'$$

### Model Complexity of Ridge Versus OLS

#### **OLS Case**

Number of free parameters equals number of parameters p.

### Ridge is more complicated

Even though there are p parameters they are constrained!

Idea: use trace of  $H(\lambda)$ 

$$\mathsf{df}(\lambda) = \mathsf{tr}\left\{H(\lambda)\right\} = \mathsf{tr}\left\{X(X'X + \lambda I_p)^{-1}X'\right\}$$

Why? Works for OLS:  $\lambda = 0$ 

$$df(0) = tr\{H(0)\} = tr\{X(X'X)^{-1}X'\} = p$$

## Effective Degrees of Freedom for Ridge Regression

Using cyclic permutation property of trace:

$$\begin{split} \mathrm{df}(\lambda) &= \mathrm{tr} \left\{ H(\lambda) \right\} = \mathrm{tr} \left\{ X (X'X + \lambda I_p)^{-1} X' \right\} \\ &= \mathrm{tr} \left\{ U D \left( D^2 + \lambda I_p \right)^{-1} D U' \right\} \\ &= \mathrm{tr} \left\{ D U' U D \left( D^2 + \lambda I_p \right)^{-1} \right\} \\ &= \mathrm{tr} \left\{ D^2 \left( D^2 + \lambda I_p \right)^{-1} \right\} \\ &= \sum_{j=1}^p \frac{d_j^2}{d_j^2 + \lambda} \end{split}$$

- $df(\lambda) \rightarrow 0$  as  $\lambda \rightarrow \infty$
- $df(\lambda) = p$  when  $\lambda = 0$
- $df(\lambda) < p$  when  $\lambda > 0$

# Comparing OLS and Ridge Predictions

$$\widehat{y}(\lambda) = X\widehat{\beta}(\lambda) = X \left(X'X + \lambda I_p\right)^{-1} X' \mathbf{y}$$

$$= H(\lambda)\mathbf{y} = \left[UD \left(D^2 + \lambda I_p\right)^{-1} DU'\right] \mathbf{y}$$

$$= \left[\sum_{j=1}^{p} \mathbf{u}_j \left(\frac{d_j^2}{d_j^2 + \lambda}\right) \mathbf{u}_j'\right] \mathbf{y} = \sum_{j=1}^{p} \left(\frac{d_j^2}{d_j^2 + \lambda}\right) \mathbf{u}_j \mathbf{u}_j' \mathbf{y}$$

# Comparing OLS and Ridge Predictions

$$\widehat{y}(\lambda) = \sum_{j=1}^{p} \left( \frac{d_j^2}{d_j^2 + \lambda} \right) \mathbf{u}_j \mathbf{u}_j' \mathbf{y}$$

- ▶ Since X is centered,  $\mathbf{z}_j = d_j \mathbf{u}_j$  is the jth sample PC
- ▶  $d_j^2$  is proportional to the variance of the *j*th sample PC
- Prediction from regression of y on z<sub>i</sub> is:

$$\mathbf{z}_{j}(\mathbf{z}_{j}'\mathbf{z}_{j})^{-1}\mathbf{z}_{j}'\mathbf{y} = d_{j}\mathbf{u}_{j}\left(d_{j}^{2}\mathbf{u}_{j}'\mathbf{u}_{j}\right)^{-1}d_{j}\mathbf{u}_{j}'\mathbf{y} = \mathbf{u}_{j}\mathbf{u}_{j}'\mathbf{y}$$

- ▶ Ridge equivalent to regressing *y* on sample PCs of *X* but shrinking predictions to zero: higher variance PCs are shrunk less.
- OLS doesn't shrink.

## Comparing the MSE of OLS and Ridge

#### Assumptions

 $y = X\beta + \varepsilon$ , Fixed X, iid data, homoskedasticity

OLS Estimator:  $\widehat{\beta}$ 

$$\widehat{\beta} = (X'X)^{-1}X'y \implies \mathsf{Bias}(\widehat{\beta}) = 0 \quad \mathsf{Var}(\widehat{\beta}) = \sigma(X'X)^{-1}$$

Ridge Estimator:  $\widetilde{\beta}_{\lambda}$ 

$$\widehat{\beta}_{\lambda} = (X'X + \lambda I)^{-1}X'y \implies \mathsf{Bias}(\widetilde{\beta}_{\lambda}) = ? \quad \mathsf{Var}(\widetilde{\beta}_{\lambda}) = ?$$

# Calculating The Bias of Ridge Regression

X fixed (or condition or X)

$$\begin{aligned} \operatorname{Bias}(\widetilde{\beta}_{\lambda}) &= \mathbb{E}\left[ (X'X + \lambda I)^{-1}X'(X\beta + \varepsilon) - \beta \right] \\ &= (X'X + \lambda I)^{-1}X'X\beta + (X'X + \lambda I)^{-1}\underbrace{\mathbb{E}[X'\varepsilon]}_{0} - \beta \end{aligned}$$
$$&= (X'X + \lambda I)^{-1}\left[ (X'X + \lambda I)\beta - \lambda\beta \right] - \beta$$
$$&= \beta - \lambda(X'X + \lambda I)^{-1}\beta - \beta$$
$$&= -\lambda(X'X + \lambda I)^{-1}\beta$$

## Calculating The Variance of Ridge Regression

X fixed (or condition or X)

$$\begin{aligned} \operatorname{Var}(\widetilde{\beta}_{\lambda}) &= \operatorname{Var}\left[ (X'X + \lambda I)^{-1} X'(X\beta + \varepsilon) - \beta \right] \\ &= \operatorname{Var}\left[ (X'X + \lambda I)^{-1} X'\varepsilon \right] \\ &= \mathbb{E}\left[ \left\{ (X'X + \lambda I)^{-1} X'\varepsilon \right\} \left\{ (X'X + \lambda I)^{-1} X'\varepsilon \right\}' \right] \\ &= \left[ (X'X + \lambda I)^{-1} X' \right] \underbrace{\mathbb{E}[\varepsilon\varepsilon']}_{\sigma^{2}I} \left[ (X'X + \lambda I)^{-1} X' \right]' \\ &= \sigma^{2} (X'X + \lambda I)^{-1} X' X \left( X'X + \lambda I \right)^{-1} \end{aligned}$$

# Comparing the MSE of OLS and Ridge

$$\begin{split} \mathsf{MSE}(\widehat{\beta}) - \mathsf{MSE}(\widetilde{\beta}_{\lambda}) &= \left\{\mathsf{Bias}^2(\widehat{\beta}) + \mathsf{Var}(\widehat{\beta})\right\} - \left\{\mathsf{Bias}^2(\widetilde{\beta}_{\lambda}) + \mathsf{Var}(\widetilde{\beta}_{\lambda})\right\} \\ &\vdots \\ &= \lambda \underbrace{(X'X + \lambda I)^{-1}}_{M'} \underbrace{\left[\sigma^2 \left\{2I + \lambda (X'X)^{-1}\right\} - \lambda \beta \beta'\right]}_{A} \underbrace{\left(X'X + \lambda I\right)^{-1}}_{M} \end{split}$$

- $\lambda > 0$  and M is symmetric
- ▶ M is full rank  $\implies Mv \neq 0$  unless v = 0
- ► Hence:  $v'[\lambda M'AM]v = \lambda (Mv)'$

Lecture #8 – High-Dimensional Regression II

**LASSO** 

# Least Absolute Shrinkage and Selection Operator (LASSO)

Bühlmann & van de Geer (2011); Hastie, Tibshirani & Wainwright (2015)

Assume that X has been centered: don't penalize intercept!

#### Notation

$$||\beta||_2^2 = \sum_{j=1}^p \beta_j^2, \quad ||\beta||_1 = \sum_{j=1}^p |\beta_j|$$

Ridge Regression –  $L_2$  Penalty

$$\widehat{\beta}_{\textit{Ridge}} = \mathop{\arg\min}_{\beta} \; (\mathbf{y} - X\beta)'(\mathbf{y} - X\beta) + \lambda \left| |\beta| \right|_{2}^{2}$$

LASSO –  $L_1$  Penalty

$$\widehat{\beta}_{\textit{Lasso}} = \mathop{\arg\min}_{\beta} \; (\mathbf{y} - X\beta)'(\mathbf{y} - X\beta) + \lambda \left| \left| \beta \right| \right|_{1}$$

### Other Ways of Thinking about LASSO

#### Constrained Optimization

$$rg \min_{eta} (\mathbf{y} - Xeta)'(\mathbf{y} - Xeta)$$
 subject to  $\sum_{j=1}^p |eta_j| \leq t$ 

Data-dependent, one-to-one mapping between  $\lambda$  and t.

### Bayesian Posterior Mode

Ignoring the intercept, LASSO is the posterior model for  $\beta$  under

$$\mathbf{y}|X, \beta, \sigma^2 \sim N(X\beta, \sigma^2 I_n), \quad \beta \sim \prod_{j=1}^{p} \mathsf{Lap}(\beta_j|0, \tau)$$

where  $\lambda=1/ au$  and  $\mathrm{Lap}(x|\mu, au)=(2 au)^{-1}\exp\left\{- au^{-1}|x-\mu|
ight\}$ 

# Comparing Ridge and LASSO – Bayesian Posterior Modes

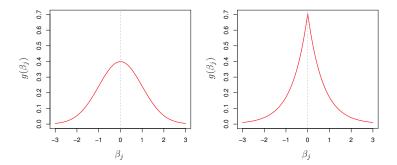

Figure: Ridge, at left, puts a normal prior on  $\beta$  while LASSO, at right, uses a Laplace prior, which has fatter tails and a taller peak at zero.

# Comparing LASSO and Ridge – Constrained OLS

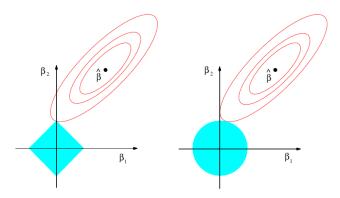

Figure:  $\widehat{\beta}$  denotes the MLE and the ellipses are the contours of the likelihood. LASSO, at left, and Ridge, at right, both shrink  $\beta$  away from the MLE towards zero. Because of its diamond-shaped constraint set, however, LASSO favors a sparse solution while Ridge does not

### No Closed-Form for LASSO!

### Simple Special Case

Suppose that  $X'X = I_p$ 

#### Maximum Likelihood

$$\widehat{\boldsymbol{\beta}}_{MLE} = (X'X)^{-1}X'\mathbf{y} = X'\mathbf{y}, \quad \widehat{\beta}_{j}^{MLE} = \sum_{i=1}^{n} x_{ij}y_{i}$$

#### Ridge Regression

$$\widehat{\boldsymbol{\beta}}_{Ridge} = (X'X + \lambda I_p)^{-1}X'\mathbf{y} = [(1+\lambda)I_p]^{-1}\widehat{\boldsymbol{\beta}}_{MLE}, \quad \widehat{\boldsymbol{\beta}}_{j}^{Ridge} = \frac{\widehat{\boldsymbol{\beta}}_{j}^{MLE}}{1+\lambda}$$

So what about LASSO?

LASSO when 
$$X'X = I_p$$
 so  $\widehat{\beta}_{MLE} = X'\mathbf{y}$ 

#### Want to Solve

$$\widehat{\boldsymbol{\beta}}_{LASSO} = \mathop{\arg\min}_{\boldsymbol{\beta}} \; (\mathbf{y} - X\boldsymbol{\beta})'(\mathbf{y} - X\boldsymbol{\beta}) + \lambda \left| \left| \boldsymbol{\beta} \right| \right|_1$$

#### **Expand First Term**

$$(\mathbf{y} - X\boldsymbol{\beta})'(\mathbf{y} - X\boldsymbol{\beta}) = \mathbf{y}'\mathbf{y} - 2\boldsymbol{\beta}'X'\mathbf{y} + \boldsymbol{\beta}'X'X\boldsymbol{\beta}$$

$$= (constant) - 2\boldsymbol{\beta}'\widehat{\boldsymbol{\beta}}_{MLE} + \boldsymbol{\beta}'\boldsymbol{\beta}$$

#### Hence

$$\begin{split} \widehat{\boldsymbol{\beta}}_{LASSO} &= \underset{\boldsymbol{\beta}}{\arg\min} \left(\boldsymbol{\beta}'\boldsymbol{\beta} - 2\boldsymbol{\beta}'\widehat{\boldsymbol{\beta}}_{MLE}\right) + \lambda \left|\left|\boldsymbol{\beta}\right|\right|_{1} \\ &= \underset{\boldsymbol{\beta}}{\arg\min} \sum_{i=1}^{p} \left(\beta_{j}^{2} - 2\beta_{j}\widehat{\boldsymbol{\beta}}_{j}^{MLE} + \lambda \left|\boldsymbol{\beta}_{j}\right|\right) \end{split}$$

## LASSO when $X'X = I_p$

### Preceding Slide

$$\widehat{\boldsymbol{\beta}}_{LASSO} \ = \ \arg\min_{\boldsymbol{\beta}} \sum_{j=1}^{p} \left(\beta_{j}^{2} - 2\beta_{j} \widehat{\beta}_{j}^{MLE} + \lambda \left| \beta_{j} \right| \right)$$

#### **Key Simplification**

Equivalent to solving j independent optimization problems:

$$\widehat{\beta}_{j}^{\textit{Lasso}} = \arg\min_{\beta_{j}} \left( \beta_{j}^{2} - 2\beta_{j} \widehat{\beta}_{j}^{\textit{MLE}} + \lambda \left| \beta_{j} \right| \right)$$

- ▶ Sign of  $\beta_i^2$  and  $\lambda |\beta_j|$  unaffected by sign $(\beta_j)$
- $ightharpoonup \widehat{eta}_i^{MLE}$  is a function of data only outside our control
- ▶ Minimization requires matching sign( $\beta_i$ ) to sign( $\widehat{\beta}_i^{MLE}$ )

# LASSO when $X'X = I_p$

Case I: 
$$\widehat{\beta}^{MLE} > 0 \implies |\beta_j| = |\beta_j| = |\beta_j|$$

Optimization problem becomes

$$\widehat{\beta}_{j}^{\textit{Lasso}} = \arg\min_{\beta_{j}} \, \beta_{j}^{2} - 2\beta_{j} \widehat{\beta}_{j}^{\textit{MLE}} + \lambda \beta_{j}$$

Interior solution:

$$\widehat{\beta}_j = \widehat{\beta}_j^{MLE} - \frac{\lambda}{2}$$

Can't have 
$$\beta_j < 0$$
: corner solution sets  $\beta_j = 0$  
$$\widehat{\beta}_j^{\textit{Lasso}} = \max \left\{ 0, \widehat{\beta}_j^{\textit{MLE}} - \frac{\lambda}{2} \right\}$$

# LASSO when $X'X = I_p$

Case II: 
$$\widehat{\beta}^{MLE} \leq 0 \implies \beta_j \leq 0 \implies |\beta_j| = -\beta_j$$

Optimization problem becomes

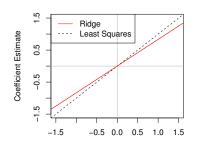

$$\widehat{\beta}_{j}^{\textit{Lasso}} = \mathop{\arg\min}_{\beta_{j}} \, \beta_{j}^{2} - 2\beta_{j} \widehat{\beta}_{j}^{\textit{MLE}} - \lambda \beta_{j}$$

Interior solution:

$$\widehat{\beta}_j = \widehat{\beta}_j^{MLE} + \frac{\lambda}{2}$$

Can't have 
$$\beta_j > 0$$
: corner solution sets  $\beta_j = 0$  
$$\widehat{\beta}_j^{\textit{Lasso}} = \min \left\{ 0, \widehat{\beta}_j^{\textit{MLE}} + \frac{\lambda}{2} \right\}$$

# Ridge versus LASSO when $X'X = I_p$

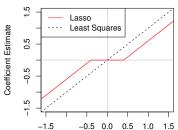

Figure: Horizontal axis in each plot is MLE

$$\begin{split} \widehat{\beta}_{j}^{\textit{Ridge}} &= \left(\frac{1}{1+\lambda}\right) \widehat{\beta}_{j}^{\textit{MLE}} \\ \widehat{\beta}_{j}^{\textit{Lasso}} &= \operatorname{sign}\left(\widehat{\beta}_{j}^{\textit{MLE}}\right) \max \left\{0, \left|\widehat{\beta}_{j}^{\textit{MLE}}\right| - \frac{\lambda}{2}\right\} \end{split}$$

## Calculating LASSO – The Shooting Algorithm

Cyclic Coordinate Descent

```
Data: y, X, \lambda \ge 0, \varepsilon > 0
 Result: LASSO Solution
\beta \leftarrow \mathsf{ridge}(X, \mathbf{y}, \lambda)
repeat
   \beta^{prev} \leftarrow \beta
| \mathbf{for} \ j = 1, \dots, p \ \mathbf{do} 
| \ a_j \leftarrow 2 \sum_{i=1}^n x_{ij}^2 
| \ c_j \leftarrow 2 \sum_{i=1}^n x_{ij} (y_i - \mathbf{x}_i'\beta + \beta_j x_{ij}) 
| \ \beta_j \leftarrow \operatorname{sign}(c_j/a_j) \max \{0, |c_j/a_j| - \lambda/a_j\} 
           end
until \sum_{i=1}^{p} |\beta_i^{prev} - \beta_j| < \varepsilon;
```
